Epimorphisms and acyclic maps

<table>
<thead>
<tr>
<th>Definition (Epimorphism)</th>
<th>Lemma</th>
</tr>
</thead>
<tbody>
<tr>
<td>A map $f : A \to B$ is an <strong>epimorphism</strong> if for every type $X$, the precomposition map $(B \to X) \xrightarrow{f^*} (A \to X)$ is an embedding.</td>
<td>A map $f : A \to B$ is epic if and only if the square $\begin{array}{ccc} A &amp; \xrightarrow{f} &amp; B \ f \downarrow &amp; &amp; \downarrow \text{id} \ B &amp; \xrightarrow{\text{id}} &amp; B \end{array}$ is a pushout.</td>
</tr>
</tbody>
</table>

So extensions along epimorphisms are unique if they exist.

<tbody>
<tr>
<td>A type is <strong>acyclic</strong> if its suspension is contractible; a map is <strong>acyclic</strong> if all its fibers acyclic.</td>
<td>For all $f : A \to B$, $b : B$: $\text{fib}_{\nabla f}(b) \simeq \Sigma \text{fib}_f(b)$.</td>
</tr>
</tbody>
</table>

**Corollary**

A map is epic if and only if it is acyclic.
Hatcher’s 2-dimensional example

**Proposition**

Acyclic types are connected with perfect fundamental groups.

**Proposition**

The unit type is an acyclic type, and equivalences are acyclic maps.

A non-trivial example of an acyclic type can be found in Hatcher’s book [Hat02, Ex. 2.38]:

We import this as the higher inductive type $X$ with constructors:

$$pt : X, \ a, b : \Omega X, \ r : a^5 = b^3, \ s : b^3 = (ab)^2$$

**Proposition**

The type $X$ is acyclic.

**Proof.**

$\Sigma X$ is the HIT with constructors $N, S : \Sigma X$, $m_{pt} : N = S$, $a, b : m_{pt} = m_{pt}$, $r : a^5 = b^3$, $s : b^3 = (ab)^2$.

Contract away $(S, m_{pt})$, then use Eckmann–Hilton to re-express $s$ as $s : b = a^2$. Then contract away $(b, s)$, so $r : a^5 = a^6$, equivalently, $r : a = \text{refl}$. Finally, contract away $(a, r)$, leaving the unit type. $\square$

Interpreting $a$ as a 5-cycle and $b$ as a 3-cycle, we get a 0-connected map $X \to BA_5$. 
### Closure properties

#### Proposition

*If* $f : A \to B$ *is acyclic, then* $g : B \to C$ *is acyclic if and only if* $g \circ f$ *is.*

#### Proposition

Acyclic maps are closed under pullbacks and pushouts along arbitrary maps.

#### Proposition

The acyclic maps are stable under composition, retracts, finite products, and all coproducts and pushouts in the arrow category.

Acyclic types are not closed under coproducts ($1 + 1$ is not acyclic), nor identity types, nor truncations.

Classically, the acyclic maps form left class of an orthogonal factorization system, via Quillen’s plus construction, $X \to X^+$, an acyclic map killing the perfect core of $\pi_1 X$.

⇝ Algebraic K-Theory

The Volodin space $X(R)$ of a ring $R$ is the fiber of $\text{BGL}(R) \to \text{BGL}(R)^+$, and hence acyclic. We have $\pi_1 X(R) \cong \text{St}(R)$, the Steinberg group. This is not acyclic, since $H_3(\text{St}(R)) \cong K_3(R)$, [Wei13, Ex. 1.9].

(Quillen) $K_3(\mathbb{F}_q) \cong \mathbb{Z}/(q^2 - 1)$, so the 1-truncation of an acyclic type need not be acyclic.
The plus principle

We don’t know whether the factorization system can be constructed in HoTT. Many properties seem to need further axioms, like:

**Plus Principle (PP)**

*Every acyclic and simply connected type is contractible.*

Hoyois highlighted this in the context of Grothendieck \((\infty, 1)\)-toposes [Hoy19, Rem. 4]. It’s open whether it holds in all such; (PP) holds in parametrized spectra and follows from Whitehead’s Principle (WP) via:

**Lemma (PP)**

*Any acyclic 1-equivalence is an equivalence.*

**Proposition (PP)**

*Let \(f : A \to B\) be acyclic, and let \(f' : A \to X\) be any map. Then \(f'\) extends along \(f\) if (and only if) \(\ker(\pi_1(f)) \subseteq \ker(\pi_1(f'))\).*

**Proof.**

Form the pushout:

\[
\begin{array}{c}
A & \xrightarrow{f'} & X \\
\downarrow f & & \downarrow g \\
B & \to & P
\end{array}
\]

Then \(g\) is an acyclic 1-equivalence.
The Higman group

An interesting acyclic 1-type is the classifying type of the Higman group [Hig51]:

\[ H = \langle a, b, c, d \mid a = [d, a], b = [a, b], c = [b, c], d = [c, d] \rangle. \]

Let BH be the HIT for the presentation complex, with nine constructors and no truncation.

**Proposition**

The type BH is acyclic.

To show BH $\not\cong \mathbf{1}$, we use the following [Wär23].

**Theorem (Wärn)**

If $A \leftarrow R \rightarrow B$ is a span of 0-truncated maps of 1-types, then the pushout $A +_R B$ is a 1-type and the inclusion maps are 0-truncated.

Let $B\langle x_i \rangle$ be the sub-HIT of BH using only constructors involving the $x_i$. Then:

\[
\begin{array}{ccc}
B\langle b \rangle & \longrightarrow & B\langle b, c \rangle \\
\downarrow & \mathsf{r} & \downarrow \\
B\langle a, b \rangle & \longrightarrow & B\langle a, b, c \rangle \\
\end{array}
\]

And $B\langle a, b \rangle$ is an HNN-extension (i.e., coequalizer of groupoids):

\[
\begin{array}{ccc}
\mathbb{S}^1 & \overset{b}{\longrightarrow} & B\langle b \rangle \\
\downarrow & \mathsf{r} & \downarrow \\
\mathbb{B}^2 & \longrightarrow & B\langle a, b \rangle \\
\end{array}
\]

So $B\langle a, b \rangle$ (with $\pi_1$ a Baumslag–Solitar group) is a 1-type and $B\langle b \rangle \rightarrow B\langle a, b \rangle$ is 0-truncated. We have section/retraction $B\langle a \rangle \rightleftarrows B\langle a, b \rangle$, so the other inclusion is 0-truncated, too.
The Higman group, continued

It remains to see that the maps of the form $B\langle a, c \rangle \to B\langle a, b, c \rangle$ are 0-truncated. The follows by descent from looking at the commuting cube:

![Commuting cube diagram]

The top and bottom faces are pushouts, and the back faces are pullbacks, so the front faces are pullbacks as well. Since the front bottom maps are (individually and jointly) surjective, and the maps on the sides are 0-truncated, the map in front is as well, as desired.

NB This proof completely avoids classical combinatorial group theory!
Using (PP), a map is acyclic if and only if it is balanced [Rap19].

This implies that the fiber sequence of an acyclic map of connected types is a cofiber sequence.

Again with (PP), we have $A \perp X$ for acyclic $A$ and hypoabelian $X$ (i.e., $\pi_1 X$ has no perfect subgroups).

Outright, we have $A \perp X$ for acyclic $X$ and nilpotent $X$ that are limits of their Postnikov towers.

With (WP), a type is acyclic if and only if its integral homology is trivial.

We also study $k$-epimorphisms and $k$-acyclic types.

We can construct (a candidate for) $BA_5^+ -$ correct assuming (WP), what about without?

We believe that plus-constructions can always be performed assuming (WP), Sets Cover (SC), and Countable Choice (CC).

Also to do: look at acyclicity of $BAut(\mathbb{N})$ and $B\Sigma_\infty \to Q_0S^0 \simeq B\Sigma_\infty^+$. 

Thank you!
